(54) Title: METHODS FOR TREATING AUTOIMMUNE DISEASES USING A TAC1-IG FUSION MOLECULE

(57) Abstract: In various embodiments, the present invention provides methods and compositions for treatment of autoimmune diseases, including rheumatoid arthritis, for example comprising administering to a patient in need of such treatment a TAC1-Ig fusion molecule. In one embodiment, the TAC1-Ig fusion molecule is administered in amount sufficient to slow, suppress or inhibit proliferation-inducing functions of B1yS and APRIL.

## **METHODS FOR TREATING AUTOIMMUNE DISEASES USING A TACI-IG FUSION MOLECULE**

### **CROSS-REFERENCE TO RELATED APPLICATIONS**

[0001] This application claims the benefit of U.S. Provisional Application No. 60/747,270, filed May 15, 2006, the contents of which is incorporated herein by reference.

### **FIELD OF THE INVENTION**

[0002] In various embodiments, the present invention relates to methods and compositions for the treatment of autoimmune diseases or disorders of the immune system, comprising administering a TACI-Ig fusion protein which blocks functions of growth factors of the TNF family.

### **BACKGROUND OF THE INVENTION**

#### **The BlyS Ligand/Receptor Family**

[0003] Three receptors, TACI (transmembrane activator or Calcium-Modulating Cyclophilin Ligand-interactor), BCMA (B-cell maturation antigen) and BAFF-R (receptor for B-cell activating factor, belonging to the TNF family), have been identified that have unique binding affinities for the two growth factors BlyS (B-lymphocyte stimulator) and APRIL (a proliferation-inducing ligand) (Marsters et al. Curr Biol 2000; 10(13): 785-788; Thompson et al. Science 2001; 293:21 08-2111). TACI and BCMA bind both BLyS and APRIL, while BAFF-R appears capable of binding only BLyS with high affinity (Marsters et al. Curr Biol 2000; 10(13):785-788; Thompson et al. Science 2001; 293:21 08-2111.). As a result, BLyS is able to signal through all three receptors, while APRIL only appears capable of signaling through TACI and BCMA. In addition, circulating heterotrimer complexes of BLyS and APRIL (groupings of three proteins, containing one or two copies each of BLyS and APRIL) have been identified in serum samples taken from patients with systemic immune-based rheumatic diseases, and have been shown to induce B-cell proliferation in vitro (Roschke et al. J Immunol 2002; 169: 4314-4321). Amongst

the Ig-fusion proteins for all three receptors, only TACI-Fc5 was able to block the biological activity of the heterotrimeric complexes (Roschke et al. J Immunol 2002; 169: 4314-4321).

[0004] BLyS and APRIL are potent stimulators of B-cell maturation, proliferation and survival (Gross et al. Nature 2000; 404: 995-999. Gross et al. Immunity 2001; 15(2): 289-302. Groom et al. J Clin Invest 2002; 109(1): 59-68). BLyS and APRIL may be necessary for persistence of autoimmune diseases, especially those involving B-cells. Transgenic mice engineered to express high levels of BLyS exhibit immune cell disorders and display symptoms similar to those seen in patients with Systemic Lupus Erythematosus (Cheson et al. Revised guidelines for diagnosis and treatment. Blood 1996; 87:4990-4997. Cheema et al. Arthritis Rheum 2001; 44(6):1313-1319). Similarly, increased levels of BLyS/APRIL have been measured in serum samples taken from SLE patients and other patients with various autoimmune diseases like Rheumatoid Arthritis (Roschke et al. J Immunol 2002; 169:4314-4321; Mariette X., Ann Rheum Dis 2003; 62(2):168-171; Hahne et al. J Exp Med 1998; 188(6):1185-1190), extending the association of BLyS and/or APRIL and B-cell mediated diseases from animal models to humans.

### **Rheumatoid Arthritis**

[0005] Rheumatoid Arthritis (RA) is a chronic inflammatory disease characterized by non-specific, usually symmetric inflammation of the peripheral joints, potentially resulting in progressive destruction of articular and periarticular structures. About 1% of the population is affected, women two to three times more often than men. Although the precise etiology of the disease is elusive, strong evidence suggests RA is an autoimmune disease. Several auto-antibodies are associated with RA including rheumatoid factor (RF) which is frequently associated with more severe disease, anti-nuclear factors and antibodies against native collagen type II and citrullinated peptides.

[0006] Prominent immunologic abnormalities that may be important in the pathogenesis of RA include immune complexes found in joint fluid cells and in vasculitis. Contributing to these complexes are antibodies (such as RF) produced by plasma cells and T helper cells that infiltrate the synovial tissue and which can produce pro-inflammatory cytokines. Macrophages and their cytokines (e.g. TNF, GM-CSF) are also abundant in diseased synovium. Increased levels of adhesion molecules contribute to inflammatory cell emigration and retention in the synovial

tissue. Increased macrophage-derived lining cells are also prominent, along with some lymphocytes.

[0007] The role of T cells in the pathogenesis of RA is well established, while that of B cells is less well known. Nevertheless, B cells play many potential roles in the pathogenesis of RA, including acting as antigen-presenting cells, secreting pro-inflammatory cytokines, producing rheumatoid factor auto-antibody and activating T cells. The potential role of B cells is further supported by the positive results of clinical trials testing rituximab, a monoclonal antibody directed against CD20, in RA patients, most notably when given in combination with methotrexate or cyclophosphamide. These findings suggest that B cells are an appropriate target for therapeutic intervention in RA.

[0008] Established treatments of RA include disease modifying anti-rheumatic drugs (DMARD) such as hydroxychloroquine, sulfasalazine, methotrexate, leflunomide, rituximab, infliximab, azathioprine, D-penicillamine, Gold (oral or intramuscular), minocycline and cyclosporine, corticosteroids such as prednisone and non-steroidal anti-inflammatory drugs (NSAIDS). These treatments are generally nonspecific, are frequently associated with serious side-effects and do not significantly affect the progression of joint destruction. Consequently, there is a long-felt need in the art to develop new methods for treating RA.

## **SUMMARY OF THE INVENTION**

[0009] In various embodiments, the present invention is directed to methods of treating autoimmune diseases. Illustratively, the methods of the invention include administering to a patient a composition comprising a human immunoglobulin-constant domain and TACI extracellular domain or a fragment thereof which binds BlyS and/or APRIL.

[0010] In another embodiment, the invention comprises methods of treating autoimmune diseases, including RA, using a TACI-Ig fusion molecule that comprises the TACI extracellular domain or any fragment thereof that retains the ability to bind BlyS and/or APRIL.

[0011] In another embodiment, the invention comprises methods of treating RA comprising administering to a patient in need thereof, an effective amount of a fusion molecule comprising a human immunoglobulin-constant chain and TACI extracellular domain or a fragment of TACI extracellular domain that binds BlyS and/or APRIL. In one embodiment, the fragment of the extracellular domain of TACI comprises one or two cysteine repeat motifs. In another

embodiment, the fragment is a fragment comprising amino acids 30-110 of the extracellular domain of TACI. In yet another embodiment, the fragment is a fragment comprising amino acids 1-154 of the extracellular domain of TACI (SEQ ID NO: 1).

[0012] In another embodiment, the invention comprises methods of treating RA by administering to a patient a composition comprising a fusion polypeptide, TACI-Fc5, comprising a human immunoglobulin-constant domain, Fc5, having the sequence set out as SEQ ID NO: 2 and a TACI extracellular domain having the sequence set out as SEQ ID NO: 1.

[0013] In still another embodiment, the invention comprises methods of treating RA by administering to a patient a composition comprising a fusion polypeptide comprising a human immunoglobulin-constant domain with the sequence set out as SEQ ID NO: 2 and a polypeptide which binds BlyS and/or APRIL and which is at least about 50%, at least about 60%, at least about 65%, at least about 70%, at least about 75%, at least about 80%, at least about 85%, at least about 90%, at least about 95% or at least about 99% identical to SEQ ID NO: 1.

[0014] Other autoimmune diseases can be treated by the methods of the invention by administering to a patient a fusion polypeptide comprising a human immunoglobulin-constant chain and TACI extracellular domain or a fragment of TACI extracellular domain that binds BlyS and/or APRIL. Such autoimmune diseases include, but are not limited to systemic lupus erythematosus (SLE), Graves disease, type I and type II diabetes, multiple sclerosis, Sjogren syndrome, scleroderma, glomerulonephritis, transplant rejection, e.g., organ and tissue allograft and xenograft rejection and graft versus host disease.

[0015] In one embodiment, the methods of the instant invention comprise administering to a RA patient a TACI-Ig fusion molecule in amounts from about 0.01 mg/kg of patient's body weight to about 10 mg/kg of patient's body weight. The TACI-Ig fusion molecule can be administered repeatedly at predetermined intervals. Illustratively, the molecule can be administered 7 or more times during a 12-week interval. This initial treatment with a TACI-Ig fusion polypeptide can be followed by administering the polypeptide on a bi-weekly (every other week) basis for at least 2 more additional weeks, for example the polypeptide can be administered on a bi-weekly basis for an additional 2 to 30 weeks. Alternately, the polypeptide may be administered on a weekly or daily basis.

[0016] According to the methods of the instant invention, a TACI-Ig fusion polypeptide can be administered to a RA patient subcutaneously, orally or intravenously and in combination with

other medicaments. Such medicaments include, but are not limited to: DMARDs such as hydroxychloroquine, sulfasalazine, methotrexate, leflunomide, rituximab, infliximab, azathioprine, D-penicillamine, Gold (oral or intramuscular), minocycline and cyclosporine, corticosteroids such as prednisone, NSAIDs, cytokines, anti-cytokines and interferons.

## **BRIEF DESCRIPTION OF THE FIGURES**

[0017] Figure 1. Dose-escalation decision tree for TACI-Fc5 treatment.

[0018] Figure 2. Diagram of patient's body areas that can be used for subcutaneous injections of TACI-Ig molecule.

## **DETAILED DESCRIPTION OF THE INVENTION**

[0019] In various embodiments, the instant invention pertains to methods of treating an autoimmune disease in a patient by inhibiting interaction of BlyS and/or APRIL with their receptors. The patient may be a mammal, for example a human. In one embodiment, the methods utilize an inhibitor that comprises: 1) a polypeptide that comprises a domain which is at least partially identical to TACI extracellular domain or a fragment thereof that binds BlyS and/or APRIL; and 2) a human immunoglobulin constant chain. In one embodiment, the methods of the invention utilize a fusion molecule comprising a human immunoglobulin constant chain and any polypeptide with at least about 50%, at least about 60%, at least about 65%, at least about 70%, at least about 75%, at least about 80%, at least about 85%, at least about 90%, at least about 95% or at least about 99% sequence identity to TACI extracellular domain. U.S. Patent Nos. 5,969,102, 6,316,222 and 6,500,428 and U.S. patent applications 09/569,245 and 09/627,206 (teachings of which are incorporated herein in their entirety by reference) disclose sequences for the extracellular domain of TACI as well as specific fragments of the TACI extracellular domain that interact with TACI ligands, including BlyS and APRIL. One illustrative fragment of the extracellular domain of TACI comprises one or two cysteine repeat motifs. Another illustrative fragment is a fragment comprising amino acids 30-110 of the extracellular domain of TACI or fragments thereof. Yet another illustrative fragment is a fragment comprising amino acids 1-154 of the extracellular domain of TACI (SEQ ID NO: 1) or fragments thereof.

[0020] Other fusion molecules useful for the methods of the invention include: a fusion polypeptide between a human immunoglobulin constant chain and the complete TACI extracellular domain or its ortholog or a fusion polypeptide between a human immunoglobulin constant chain and any fragment of the extracellular TACI domain that can bind BlyS and APRIL ligands. Any of the fusion molecules used in the methods of the invention can be referred to as a TACI-Ig fusion molecule.

[0021] TACI-Fc5 is one of the TACI-Ig fusion molecules useful for the methods of the invention. TACI-Fc5 is a recombinant fusion polypeptide comprising the extracellular, ligand-binding portion of receptor TACI from about amino acid 1 to about amino acid 154 (SEQ ID NO: 1) and the modified Fc portion of human IgG, Fc5 (SEQ ID NO: 2). Other TACI-Ig molecules useful for the methods of the instant invention include a fusion molecule comprising polypeptide with SEQ ID NO: 2 and a polypeptide which can bind BlyS and which is at least about 50%, at least about 60%, at least about 65%, at least about 70%, at least about 75%, at least about 80%, at least about 85%, at least about 90%, at least about 95% or at least about 99% identical to SEQ ID NO: 1.

[0022] Embodiments of the instant invention comprise methods of using a TACI-Ig fusion molecule for treating RA. Other autoimmune diseases that can be treated with the methods of the invention include systemic lupus erythematosus (SLE), Graves disease, type I and type II diabetes, multiple sclerosis, Sjogren syndrome, scleroderma, glomerulonephritis, transplant rejection, e.g., organ and tissue allograft and xenograft rejection, graft versus host disease or any other autoimmune disease that may be treated by decreasing the number of circulating mature B-cells and immunoglobulin-secreting cells and soluble immunoglobulins associated with such diseases.

[0023] Embodiments also comprise methods of treatment by administering to a patient a fusion molecule comprising a human immunoglobulin-constant domain and a polypeptide comprising any fragment of TACI extracellular domain that can bind BlyS and/or APRIL.

[0024] A TACI-Ig fusion molecule can be administered to a patient according to any suitable route of administration, including by not limited to orally, intravenously or subcutaneously.

[0025] TACI-Ig formulations useful for the methods of the invention can be prepared and stored as a frozen, sterile, isotonic solution. Such formulations can include other active ingredients and excipients such as, for example, sodium chloride, phosphate buffer and sodium

hydroxide or O-phosphoric acid (pH 6.0). TACI-Ig formulations can be administered to a patient in combination with other medicaments. Such medicaments include, but are not limited to DMARDs such as hydroxychloroquine, sulfasalazine, methotrexate, leflunomide, rituximab, infliximab, azathioprine, D-penicillamine, Gold (oral or intramuscular), minocycline and cyclosporine, corticosteroids such as prednisone, NSAIDs and drugs for the management of pain. Methods of the invention can be used in combination with other methods of treating autoimmune diseases. Such other methods of treatment include, but are not limited to surgery, acupuncture, physical therapy and gene therapy. TACI-Ig formulations can be administered prior, simultaneously or subsequently to other methods of treatment.

[0026] TACI-Fc5 has been shown to inhibit BLYS activation of B cell proliferation *in vitro*. Treatment of mice with TACI-Fc5 results in a partial block in B cell development that has a minimal effect on B cell precursors in the bone marrow and other cell lineages including peripheral blood T cells, monocytes and neutrophils. Transgenic mice engineered to over-express a soluble form of the TACI receptor in the blood produce fewer mature B cells and show reduced levels of circulating antibody. The TACI-Fc5 transgenic mice had normal numbers of cells in the thymus, bone marrow and mesenteric lymph node. There were no significant differences in T cell populations in the thymus, lymph node and spleen. (Gross et al. Immunity 2001; 15(2): 289-302.)

[0027] Further, TACI-Ig can inhibit antigen-specific antibody production in an immune response in mice whether administered during the primary response or the secondary response to an antigen. In these studies, no effect on T cell response to *ex vivo* antigenic challenge was observed. In an animal model of systemic lupus erythematosus, treatment with TACI-Ig fusion proteins was effective in limiting the onset and progression of the disease. (Gross et al. Nature 2000; 404: 995-999). Similarly, in a mouse model of collagen-induced arthritis, TACI-Ig was able to inhibit the development of collagen-specific antibodies and reduce both the incidence of inflammation and the rate of occurrence of disease. (Gross et al. Immunity 2001; 15(2): 289-302).

[0028] A composition comprising a TACI-Ig fusion molecule may be administered to a patient once or may be administered to a patient repeatedly over a period of time. For example, a patient may receive one subcutaneous injection of TACI-Ig molecules after which his or her condition may be monitored. Patients who demonstrate improvement or at least stabilization of their

condition may be administered a TACI-Ig fusion molecule repeatedly for an additional period of time. The additional period of time may be from about 2 to about 30 weeks. For example, a patient may be administered three doses of TACI-Ig fusion molecule during a four week interval. Alternately, a patient may be administered seven doses of a TACI-Ig fusion molecule during a twelve week interval. The administration of TACI-Ig molecules to a patient may be daily, bi-daily, weekly, bi-weekly, monthly, bi-monthly, *etc.*

[0029] A TACI-Ig fusion molecule is administered to a patient in amount that is efficient for treating the patient's condition. In one embodiment, the term "treating" in relation a given disease or disorder, includes, but is not limited to, inhibiting the disease or disorder, for example, arresting the development of the disease or disorder; relieving the disease or disorder, for example, causing regression of the disease or disorder; or relieving a condition caused by or resulting from the disease or disorder, for example, relieving, preventing or treating symptoms of the disease or disorder. In another embodiment, the amount may range from 0.01 mg per 1 kg of patient's body weight to 10 mg per 1 kg of patient's body weight. An optimal dose for treating with a TACI-Ig fusion molecule can be developed by using a diagram of Figure 1, described in further detail in Example 5.

[0030] A fusion TACI-Ig molecule may be delivered in any suitable manner. In one embodiment, the molecule is delivered by peritoneal injection. In another embodiment, the peritoneal injection is via subcutaneous injection. In another embodiment, the peritoneal injection is administered into the anterior abdominal wall. When more than one injection is required to administer a dose, the injections can be administered a few centimeters apart and relatively close together in time, for example as close as is reasonably possible. For repeated drug administration, the site of administration on the anterior abdominal wall can be rotated or alternated. Exemplary zones for subcutaneous injection into the anterior abdominal wall are depicted in Figure 2 and include right upper external area, left lower external area, right lower external area, left upper external area, median lower area as well as right and left thighs and upper arms (Figure 2). Alternatively, a TACI-Ig fusion molecule of the instant invention may delivered via intravenous injections or orally in a form of tablets, caplets, liquid compositions or gels, *etc.*

### Example 1

### **Testing TACI-Fc5 Pharmacology, Toxicology and Pharmacokinetics in an Experimental Animal Model.**

[0031] TACI-Fc5 was evaluated in a host resistance model that provided the opportunity to directly assess the functional reserve of the immune system. Mice were challenged with influenza virus during TACI-Fc5 treatment. Dexamethasone, used as a positive control, resulted in an enhanced and prolonged viral infection. Administration of a single dose of TACI-Fc5 by the subcutaneous (SC) route reduced circulating B cells, total IgG and IgM, and influenza-specific IgG and IgM, but did not decrease the animals' ability to clear the viral infection.

[0032] Pivotal Safety Pharmacology studies showed that TACI-Fc5 induced no major changes of the nervous, respiratory and cardiovascular systems in mice or monkeys up to the SC dose of 80 mg/kg. Only in mice, a slightly increased hyper-alertness and locomotor activity, that may suggest minor and transient stimulant effect, was seen at 80 mg/kg, with a No-observed effect level (NOEL) equal to 20 mg/kg.

[0033] When administered to mice as a single dose by the intravenous (IV) or SC route, TACI-Fc5 did not induce mortality or appreciable general or local abnormal effects in the animals up to the highest technically feasible dose: 1200 mg/kg.

[0034] The administration to monkeys of TACI-Fc5 as a single dose by the SC route at the dose level of 240 mg/kg did not result in mortality or in any major toxic effects.

[0035] On the basis of the results obtained after 2 or 4 weeks of administration of TACI-Fc5 by subcutaneous route to mice at the doses of 5, 20 and 80 mg/kg/every second day, it may be concluded that the compound is well tolerated in this species at doses up to 80 mg/kg.

Treatment-related modifications confined to the immune system were revealed at all doses. These changes involved decreases in total and mature B cell numbers and IgG and IgM serum levels. Immunohistochemistry tests done in the spleen and lymph nodes confirmed depletion confined to B cells, with T cell number being unchanged. All these alterations, time- and dose-related in some cases, were considered as exaggerated pharmacological effects as expected in a responsive species after administration of very high doses of TACI-Fc5. Overall, these effects were seen after 2 and 4 weeks of treatment, without major indications of progression with time. They appeared to be almost completely reversible after 4 weeks of withdrawal of treatment, except for decreased B cell counts.

[0036] In order to ascertain B-cell modulation reversibility, a further study in mice was conducted at the doses of 5 and 20 mg/kg given for 4 weeks every 2nd day, with longer recovery periods. Recovery of total and mature circulating B cells was reached after two months of withdrawal at 5 mg/kg, and after 4 months at 20 mg/kg. Moreover, the injection induced a slight increase, compared to vehicle controls, of inflammatory changes at the injection sites at all doses.

[0037] Subcutaneous administration of TACI-Fc5 in monkeys did not induce major signs of toxicity at any of the doses tested: 5, 20 or 80 mg/kg/every 3rd day, when given for four consecutive weeks.

[0038] Local tolerability was considered satisfactory up to and including the highest dose tested. Dose-related and reversible slight or moderate changes of inflammatory origin (mainly perivascular mononuclear and eosinophilic cell infiltrates) were induced, but were considered mainly related to the local presence of exogenous proteins. Only at the high dose, a few animals showed slight or moderate subacute inflammation associated with a cyst formation in one of them.

[0039] Circulating B-cell number decreases at the lymphocyte subset determinations, as well as histological depletion of the spleen follicular marginal zone (known to be a B-cell dependent area) and decreases in total IgG and IgM serum levels were seen. They were considered a result of the pharmacodynamic properties of TACI-FcS, as shown by *in vitro* and *in vivo* pharmacology experiments. Their degree was exaggerated, as expected in toxicology studies in which animals are purposely administered high doses of the test compound. While low serum IgG and IgM levels and spleen lymphocytic depletion showed a clear tendency towards recovery within the one month withdrawal period allowed, total and mature circulating B cells did not show a similar behavior, indicating a longer time needed to recover.

[0040] At the end of the treatment period (week four), males and females of the high dose group (80 mg/kg) showed a slight but statistically significant decrease in mean total protein values compared to controls. A slight trend towards decrease was also seen at the same dose in week two, and at the end of the recovery period.

[0041] Serum protein modifications in the high dose females at the end of the dosing period included a decrease in globulin and increases in albumin percentage and alpha-1-globulin

fraction. Alpha-1-globulin fraction also appeared higher than controls in group 3 females (20 mg/kg).

[0042] Immunogenicity of TACI-FcS was low in both mice (only a few females showed low levels of circulating binding antibodies during and after the treatment period) and monkeys (low levels were found after the recovery period in a few animals); there was no evidence of neutralizing antibodies in either species.

[0043] TACI-Fc5 was tested with the standard battery of *in vivo* tests to detect toxicology of reproduction and fertility (fertility test in male and female mice, treated by sc route at the doses of 5, 20 and 80 mg/kg/every 2nd day before and during the mating and up to the implantation period) and embryo-fetal development (embryo-fetal development study in female mice and rabbits, treated by sc route at the doses of 5, 20 and 80 mg/kg/every 2nd day during the organogenesis period).

[0044] The fertility test in mice showed a dose-related increase in pre- and post-implantation losses following exposure to 20 and 80 mg/kg/every 2nd day of TACI-Fc5 compared to the control group.

[0045] Evaluation of the data obtained in mice of the embryo-fetal development study showed that no embryo-toxic effects were seen at any dose, and no compound-related fetal malformations were induced.

[0046] In rabbits, the embryo-fetal development study showed that treatment caused a dose-related lower body weight gain and lower food consumption in the pregnant animals treated with 20 or 80 mg/kg/every 2nd day. The above maternal changes were associated with an increased rate of resorptions and lower fetal body weight at the two higher doses.

[0047] These results suggest a possible effect of TACI-Fc5 on implantation of the mouse blastocyst in the uterus. The observed effects of TACI-Fc5 on maternal weight gain and food consumption were likely responsible for the observed effects on litter viability in rabbits exposed to 20 or 80 mg/kg/every 2nd day during organogenesis and that there is no direct toxicity of TACI-Fc5 on the fetus. No malformations were attributed to TACI-Fc5 treatment in these two animal species.

[0048] In addition, histological examination of male and female gonads and accessory sex organs was conducted in the 2-week and 1-month toxicity studies done by sc route in mice and

monkeys in which TACI-Fc5 was administered every 2nd or every 3rd day, respectively, without evidence of treatment-related effects.

[0049] The local tolerance study in rabbits showed that TACI-Fc5 formulation was well tolerated locally when injected by the subcutaneous route to rabbits, at the dose of 70 mg/mL.

[0050] A single dose pharmacokinetic study in male mice by IV and SC routes was conducted in mice by either the intravenous route, at the dose of 1 mg/kg, or the subcutaneous route, at the doses of 1, 5 and 15 mg/kg.

[0051] Time to maximal absorption ( $t_{\max}$ ) was estimated between 4 hours to 16 hours, with a  $t_{1/2}$  calculated to be around 40-50 hours.

[0052] An infusion-like profile was observed during the first 30 minutes after IV bolus administration, after which TACI-Fc5 was eliminated from the body with an elimination half-life of 44 hours. After subcutaneous administration, the ratio between the AUCs (Area Under the Curve) obtained at the 3 doses of 1, 5 and 15 mg/kg was 1 : 5 : 8 vs. the dose ratio of 1 : 5 : 15, suggesting a loss of dose-proportionality at the high dose.

[0053] TACI-Fc5's bioavailability by the subcutaneous route was of 76 and 89% at the doses of 1 and 5 mg/kg, but was lower than expected at 15 mg/kg (0,42; calculated vs. the intravenous 1 mg/kg dose) in mice. Since the apparent elimination half-life was not altered, the lower bioavailability observed at the high dose could be explained by an increase of both clearance and volume of distribution or more probably by a decreased absorption due to the formation of a deposit at the site of injection.

[0054] A single dose pharmacokinetic study in male monkeys by IV and SC routes was conducted in male cynomolgus monkeys injected by either the intravenous route, at the dose of 1 mg/kg, or the subcutaneous route, at the doses of 1, 5 and 15 mg/kg.

[0055] Six male monkeys were divided into 2 groups of 3 animals each and received 2 administrations separated by a wash-out period of two weeks. Treatments of period 1 were 1 mg/kg IV (group 1) and 1 mg/kg SC (group 2) and treatments of period 2 were 5 mg/kg SC (group 1) and 15 mg/kg SC (group 2).

[0056] Time to maximal absorption ( $t_{\max}$ ) was estimated between 6 hours to 8 hours, with a  $t_{1/2}$  calculated to be around 120-190 hours.

[0057] An infusion-like profile was observed in 2 out of 3 monkeys during the first 15 min after IV bolus administration, after which TACI-Fc5 was eliminated from the body with an

elimination half-life of  $179 \pm 29$  hours. The volume of distribution at the steady state,  $V_{ss}$ , was  $382 \pm 82$  mL/kg, a volume near the intracellular fluid volume.

[0058] After subcutaneous administration, the AUC vs. dose proportionality was good, i.e. 216, 1182 and 2732 h  $\mu$ g/mL for SC doses of 1, 5 and 15 mg/kg. The TACI-Fc5 bioavailability by the subcutaneous route (calculated vs. the 1 mg/kg IV dose) was 0.92, 1.02 and 0.77 at the low, intermediate and high doses. Therefore, TACI-Fc5 was almost completely absorbed by the subcutaneous route.

[0059] Low levels of TACI-Fc5 were found in the pre-dose samples for period 2 (between doses of 1 mg/kg by IV or SC routes, period 1, and doses of 5 or 15 mg/kg, respectively, in period 2) for all six monkeys, since during the 2-week washout period only 2 half-lives had elapsed, which was insufficient for a complete elimination of the administered compound (5 half-lives required). However, the AUC contribution of the previous dose could be estimated to represent only about 2% of the total AUC in period 2.

[0060] IgG serum levels showed a 10.2% decrease after IV dosing. The 15 mg/kg SC dose showed a slightly higher effect, while no differences were observed between the 1 and the 5 mg/kg SC doses (decreases of 8.6%, 8.4% and 12.3% after 1, 5 and 15 mg/kg doses respectively). IgM serum levels showed an 18.0% decrease after IV dosing. No differences were observed between the 3 SC doses (decreases of 23.5%, 23.0% and 24.2% after 1, 5 and 15 mg/kg doses respectively).

## **Example 2**

### **Determining TACI-Fc5 Tolerable Dose in Healthy Volunteers**

[0061] The first phase I study of TACI-Fc5 is currently being completed. This is a double-blind, placebo controlled, dose escalating, sequential dose study investigating the safety, pharmacokinetics and pharmacodynamics of single doses of TACI-Fc5 administered subcutaneously to healthy male volunteers. An outline of the study design is presented below, along with summaries of the available data.

[0062] TACI-Fc5 was administered to healthy volunteers in a double-blind, placebo controlled, dose escalating, sequential dose study to investigate the safety, pharmacokinetics and

pharmacodynamics of single doses of TACI-Fc5 administered subcutaneously to healthy male volunteers.

[0063] Four groups of subjects were recruited. In each dosing group one subject was randomized to receive a placebo injection, with all others receiving TACI-Fc5. Following discharge from the investigational site at 24 hours post dose, subjects attended on an outpatient basis for seven weeks of scheduled assessments. Systemic and local tolerability of TACI-Fc5 were monitored by physical examination findings, injection site pain, local tolerability reactions at the site of injection(s) (redness, swelling, bruising and itching), vital signs, 12-lead ECGs (electrocardiograms), safety laboratory assessments and recording of adverse events.

[0064] Pharmacokinetic and pharmacodynamic markers were monitored throughout the seven-week period following dosing. The pharmacodynamic effect of TACI-Fc5 was monitored using a number of markers including: lymphocyte subsets by FACS analysis (plasma cells (CD138+), immature B cells (CD19+, IgD-), mature B cells (CD19+, IgD+), T-helper cells (CD5+, CD4+), cytotoxic T-cells (CD5+, CD8+), total T-cells (CD5+)), free BlyS, BlyS/TACI-Fc5 complex, IgG, IgM, anti-TACI-Fc5 antibodies.

[0065] Dose escalation was guided by an algorithm within the study protocol, based upon a review of data three weeks after dosing. Four groups were dosed: group 1 received 2.1 mg; group 2 received 70 mg; group 3 received 210 mg and group 4 received 630 mg.

[0066] Results: healthy male volunteers were administered single subcutaneous doses of TACI-Fc5 at doses ranging from 0.03 mg/kg to 9 mg/kg. Safety and tolerability data have been used, together with FACS analysis of lymphocyte subsets at week 3, to guide the dose escalation between cohorts. Four cohorts have been studied, as shown in Table 1.

**Table 1: Repartition of volunteers**

<b>Cohort Number</b>	<b>Number of Subjects<sup>C</sup></b>	<b>Dose Level</b>	<b>Administered Dose<sup>a</sup></b>
1	6	0.03 mg/kg <sup>b</sup>	2.1 mg
2	6	1 mg/kg	70 mg
3	6	3 mg/kg	210 mg
4	5 <sup>d</sup>	9 mg/kg	630 mg

<sup>a</sup> At each dose level a nominal weight of 70 kg was assumed, with subjects receiving a standardized dose.

<sup>b</sup> Due to a dilution error the dose administered to cohort 1 was 10 fold lower than had been planned (0.3 mg/kg). This error was identified upon review of pharmacokinetic data from cohort 1, but following dosing of cohort 2.

<sup>c</sup> including 1 subject on placebo.

<sup>d</sup> One volunteer withdrew before the injection took place

Demographic baseline characteristics were summarized for the population by cohort and overall and are shown in Table 2.

**Table 2: Demographic Characteristics**

Characteristic	Statistics		Cohort 1	Cohort 2	Cohort 3	Cohort 4	Total
Age (years)	n	(SD)	6	6	6	5	23
	Mean		30.2 (7.0)	33.0 (7.7)	25.3 (6.8)	35.0 (5.4)	30.7 (7.4)

Injury, poisoning and procedural complications	Contusion					1	1	2.1
	Joint Injury			1			1	2.1
Musculoskeletal and connective tissue disorders	Arthralgia		1				1	2.1
	Back Pain					1	1	2.1
Nervous system disorders	Headache	1	2	2	2	1	8	17.0
Respiratory, thoracic and mediastinal disorders	Cough		1		1	1	3	6.4
	Nasal congestion			1		1	2	4.3
	Pharyngolaryngeal pain	1	2	1	2	1	7	14.9
Skin and subcutaneous tissue disorders	Rash generalised					1	1	2.1

[0069] Transient redness and swelling was observed at the site of administration in some subjects, with redness affecting all subjects in cohorts 3 and 4. Although the incidence of injection site reactions appears to be increased in higher dose groups it is believed that this is related to the increased volume (and number) of injections.

[0070] Forty-eight (48) treatment emergent adverse events were reported in the seven weeks following dosing. The majority of these (44 events, 91.7%) were mild, with the remainder being moderate (4 events, 8.3%). There were no severe adverse events and no serious adverse events during this period. There was no apparent relationship between the doses of TACI-Fc5 administered and the incidence, intensity or assigned relationship of adverse events. The adverse events reported to date are summarized in Table 3.

[0071] TACI-Fc5 is believed to have shown good tolerability at doses up to 630 mg with no significant safety concerns being raised. These data support the intended doses of the proposed subject studies.

[0072] A non-compartmental analysis of TACI serum concentrations was performed. This preliminary analysis was performed using nominal sampling times. Subjects 2, 6 and 13 had measurable concentrations pre-dose, thus baseline concentrations were subtracted from all post-dose measurements prior to analysis. Pharmacokinetic parameters following single subcutaneous doses of 2.1, 70, 210 and 630 mg are summarized in Table 4. Drug concentrations were close to the limit of quantitation of the assay following the 2.1 mg dose of TACI-Fc5, limiting the value of the data at this dose level. At doses of 70 mg and above,  $T_{max}$  (time to maximal absorption) ranged from 16 to 36 hours and the overall median  $t_{1/2}$  (calculated from the terminal portion of the curve) was 303 hours. In addition, the AUC (extrapolated to infinity) and the  $C_{max}$  increased in a greater than dose proportional manner.

**Table 4: PK parameters**

Parameter	Treatment	n			Min	Median	Max	CV

[0073] Pharmacodynamic analyses have shown reductions in baseline IgM levels in the seven weeks following single doses of 70, 210 or 630 mg. Although no clear dose response relationship could be established with the small sample size, the extent of the IgM reduction was greatest in the highest dose group. Subjects in the 70 mg dose group appeared to show a return

of IgM levels towards baseline by seven weeks post dose. Levels in the higher dose groups remained suppressed at this time point. There were no apparent effects upon IgG levels, or upon the lymphocyte subpopulations that were measured by FACS.

There was increase in levels of BLyS/TACI-Fc5 complexes proportionately during the sampling period, reaching a plateau by approximately 600 hours post dose. Conclusion: human data obtained in healthy male volunteers have shown TACI-Fc5 is safe and well tolerated by subjects at doses up to 630 mg. The nature, incidence and severity of adverse events were comparable between TACI-Fc5 treatment groups and placebo. There were no clinically significant changes in physical examination findings, vital signs, 12-lead ECGs or in safety laboratory parameters. Local tolerability at the site of administration was good. These data support the proposed doses in subjects with BCM.

[0074] After single doses in healthy male subjects, TACI-Fc5 reached  $T_{\max}$  between 16 and 20 hours AUC increased in a dose-proportional manner, though increases in  $C_{\max}$  were greater than dose proportional. Median half-life of TACI-Fc5 was approximately 300 hours. A pharmacodynamic effect was noted upon IgM levels at doses of 70, 210 and 630 mg. There was no apparent effect of treatment upon IgG or lymphocyte subpopulations following a single dose of TACI-Fc5. There are no known or anticipated risks of particular severity or seriousness that have not already been taken into account in the proposed study protocols.

### **Example 3**

#### **Treating RA Patients with TACI-Fc5 Compositions**

[0075] RA patients are clinically assessed prior to administration of TACI-Fc5. Baseline assessments are defined as those assessments conducted immediately prior to the first administration of TACI-Fc5. The first day of TACI-Fc5 administration is designated as "Day 1". The following procedures are completed before administering to a patient the first dose of TACI-Fc5 medication: ECG; vital sign (VS) measurement; physical examination; assessment of disease activity (see Example 6); measurement of height and weight (first dose and follow up visit only); routine laboratory tests (see Table 5); calculation of urine hydroxypyridinoline/lysylpyridinoline (HP/LP) ratio; pharmacokinetic (PK) and pharmacodynamic (PD) measurement of free and total TACI-Fc5 serum concentration, serum levels of free APRIL and BlyS, BLyS/TACI-Fc5

complex, cell counts by flow cytometry and measurement of anti TACI antibodies (first dose only); and measurement of biomarkers in blood including lymphocyte subsets (blood split into three tubes and phenotyped by FACS analysis according to Table 6), IgA, IgM, IgG (including sub-typing), anti-citrullinated peptides auto-antibodies, rheumatoid factors (IgA-RF, IgM-RF, IgG-RF), C-reactive protein (CRP), TNF- $\alpha$ , IFN- $\gamma$ , IL-6, IL-1, IL-12, and IL-8. In a subset of patients arthroscopically guided synovial biopsy or synovial fluid sampling by needle puncture is performed and PK, PD and biomarker assessments are performed in the synovial fluid. In repeat dose cohorts, many or all of these measurements are performed immediately prior to subsequent administrations of TACI-Fc5.

[0076] Approximately six hours post-dose, except for cohort 6, the following assessments are made: ECG; VS; and PK and PD sampling (only for single-dose cohorts).

[0077] The treatment with TACI-Fc5 follows a sequential dose-escalation cohort design outlined in Figure 1. The first cohort receives a single 70 mg dose of TACI-Fc5 on Day 1. Subsequent cohorts receive doses based upon the dose-escalation algorithm, up to a maximal dose of 2940 mg. The second cohort receives three 70 mg doses of TACI-Fc5 during a one month period. The third cohort receives a single 210 mg dose of TACI-Fc5. The fourth cohort receives three 210 mg doses of TACI-Fc5 during a one month period. The fifth cohort receives a single 630 mg dose of TACI-Fc5. The sixth cohort receives seven 420 mg doses of TACI-Fc5 during a three month period.

[0078] Post-dose assessments, including collection of PK, PD and biomarker samples and safety and disease activity assessments, are completed from all cohorts at pre-defined intervals up to 14 weeks following dosing (single dose cohorts), up to 18 weeks following dosing (repeat dose cohorts 2 and 4) and up to 26 weeks following dosing (repeat dose cohort 6). Table 7 describes the post-dose assessment schedule, beginning on Day 2, of cohorts 1, 3 and 5 (the single dose cohorts). Table 8 describes the post-dose assessment schedule, starting with the first day after the final dose (Day 30) of cohorts 2 and 4. Table 9 describes the post-dose assessment schedule, starting on the day of administration of the second dose (Day 15) of cohort 6. Injection site reactions, adverse events and concomitant medications and procedures are measured throughout the study for all cohorts. Adverse event data is obtained at scheduled or unscheduled

study visits following physical examination, based on information spontaneously provided by the patient and through questioning of the patient.

[0079] An adverse event is defined as any untoward medical occurrence in the form of signs, symptoms, abnormal laboratory findings, or diseases that emerge or worsen relative to baseline (i.e. the initial visit), regardless of causal relationship and even if no investigational product has been administered. The severity of an adverse event may be evaluated using the following definitions: (1) mild – the patient is aware of the event or symptom, but the event or symptom is easily tolerated; (2) moderate – the patient experiences sufficient discomfort to interfere with or reduce his or her usual level of activity; (3) severe – significant impairment of functioning wherein the patient is unable to carry out usual activities; and (4) very severe – the patient's life is at risk from the event. The relationship of the adverse event to the administration of TACI-Fc5 may be evaluated using the following definitions: (1) probable – a causal relationship is clinically/biologically highly plausible and there is a plausible time sequence between the onset of the adverse effect and administration of TACI-Fc5; (2) possible – a causal relationship is clinically/biologically plausible and there is a plausible time sequence between onset of the adverse effect and administration of TACI-Fc5; (3) unlikely – a causal relationship is improbable and another documented cause of the adverse effect is most plausible; and (4) unrelated – a causal relationship can be definitively excluded and another documented cause of the adverse effect is most plausible. Medical conditions present at baseline that do not worsen in severity or frequency during the administration of TACI-Fc5 are not considered adverse events. Exacerbation of RA is captured as part of the disease assessment and is not considered an adverse event unless possibly or probably related to the administration of TACI-Fc5.

[0080] The dosage, administration schedule and route of administration of TACI-Fc5 are set forth in Table 10. Briefly, seventy-two male and female RA patients, aged between 18 and 70 years, are included. The patients have an established diagnosis of active, moderate to severe RA for at least 6 months, have failed not more than five DMARDs and have not used DMARDs other than methotrexate for 4 or more weeks prior to Day 1. Further, the patients are RF positive and are not pregnant during the study and until 3 months after the last administration of TACI-Fc5. These patients are divided into 6 cohorts. Three of the cohorts have 8 patients, two of the cohorts have 12 patients and one cohort has 24 patients.

**Table 10: Dosage and Administration of TACI-Fc5**

<b>Cohort</b>	<b>Drug regimen</b>	<b>Administration route</b>
<b>Cohort 1</b> (70 mg single dose, 8 patients)	TACI-Fc5 70 mg or matching placebo on Day 1	1 subcutaneous injection of 0.5 ml in the morning
<b>Cohort 2</b> (3 x 70 mg repeated dose in 1 month, 12 patients)	TACI-Fc5 70 mg or matching placebo on Days 1, 15 and 29	1 subcutaneous injection of 0.5 ml in the morning
<b>Cohort 3</b> (210 mg single dose, 8 patients)	TACI-Fc5 210 mg or matching placebo on Day 1	1 subcutaneous injection of 1.5 ml in the morning
<b>Cohort 4</b> (3 x 210 mg repeated dose in 1 month, 12 patients)	TACI-Fc5 210 mg or matching placebo on Days 1, 15 and 29	1 subcutaneous injection of 1.5 ml in the morning
<b>Cohort 5</b> (630 mg single dose, 8 patients)	TACI-Fc5 630 mg or matching placebo on Day 1	3 subcutaneous injection of 1.5 ml in the morning
<b>Cohort 6</b> (7 x 420mg repeated dose in 3 months, 24 patients)	TACI-Fc5 420 mg or matching placebo on Days 1, 15, 29, 43, 57, 71 and 85	2 subcutaneous injections of 1.5 ml in the morning

**Example 4****TACI- Fc5 Injection Procedure.**

[0081] If subcutaneous route of administration is chosen for delivering TACI-Fc5, then the molecule is injected subcutaneously into the abdominal wall and sites rotated per the diagram below (Figure 2). Care is taken not to inject into a blood vessel. It is extremely important to rotate sites to keep the skin healthy. Repeated injections in the same spot can cause scarring and hardening of fatty tissue. The following areas should be used for injection and rotated as follows (Figure 2): first injection into left upper external area (Figure 2, position 1); second injection into right lower external area (Figure 2, position 2); third injection into left lower external area (Figure 2, position 3); fourth injection into right upper external area (Figure 2, position 4); and fifth injection into median lower area (Figure 2, position 5). The aforementioned rotation scheme is repeated for additional injections.

[0082] For patients requiring more than one injection per dose, injection begins at the twelve o'clock position for the site area designated for that injection (as per Figure 2, sites 1 - 5) and are then rotated sequentially clockwise, 2 hours, 4 hours, 6 hours, 8 hours and/or the 10 hour

position as needed for the required number of injections per dose. Injections need to be at least 2.5 cm (1 inch) apart from each other and injected as close as possible in time. No injection of more than 1.5 mL into one injection site is allowed. If a patient experiences difficulty with injections into the abdomen, alternate areas that may be injected are anterior thighs and upper arms.

[0083] Common symptoms of site of injection reactions include itching, tenderness, warmth, and/or redness at the site of the injection.

### **Example 5**

#### **Dose Escalation Protocol for Administering TACI-Ig Molecule**

[0084] This dose escalation protocol for evaluation of TACI-Fc5 in RA allows for dosing of six patients in the first cohort. The first cohort receives a single dose of 70 mg, followed by 4 weeks of observation. A Safety Review Board (SRB) reviews safety data collected four weeks post-dose, and at the SRB's recommendation, the dosage is escalated to 210 mg, administered over 1 month (the second cohort) or as a single dose (the third cohort). Nine patients are dosed in the second cohort and six patients are dosed in the third cohort. The SRB then reviews safety data collected from the third cohort six weeks post-dose and at the SRB's recommendation, the dosage is escalated to 630 mg, administered over 1 month (the fourth cohort) or as a single dose (the fifth cohort). Nine patients are dosed in the fourth cohort and six patients are dosed in the fifth cohort. The SRB then reviews safety data collected from the fifth cohort six weeks post-dose and at the SRB's recommendation, cohort six receives 2940 mg over a 3 month period. Eighteen patients are dosed in the sixth cohort.

[0085] The dosages chosen are rationally based on repeated SC toxicology studies in cynomolgus monkeys and mice which indicated that TACI-Fc5 was well tolerated at 5, 20 and 80 mg/kg. Apart from the effects on the immune cells that are the expected results of TACI-Fc5 pharmacodynamic activity, the only findings were a significant decrease of plasma total protein and slight subcutaneous reaction with the highest SC dose of 80 mg/kg in monkeys and a transient hyperactivity in the Irwin test in mice at the dose of 80 mg/kg. Therefore, 20 mg/kg is the highest dose not associated with adverse findings in both species.

[0086] In addition, doses of 2.1, 70, 210 and 630 mg have been administered as single subcutaneous doses to healthy volunteers. There have been no safety or tolerability concerns raised at these doses. On the basis of pre-clinical data and the preliminary findings in healthy volunteers, 70 mg has been selected as an appropriate starting dose for patients with RA.

[0087] The doses and dosing regimens foreseen in the RA patients in the present study ranges from 1 mg/kg to 9 mg/kg twice a month (when normalized for a 70 kg person), which fits well with the dose range studied in monkeys. Repeated administration in monkeys has shown a clear dose-response relationship.

### **Example 6**

#### **Assessment of Disease Progression.**

[0088] Disease progression is measured by Disease Activity Score, Physician's Global Assessment of Disease Activity, Patient's Global Assessment of Disease Activity, morning stiffness and patient's assessment of pain, disease activity and physical function.

[0089] The Disease Activity Score (DAS) is a combined index that has developed to measure the disease activity in patients with RA. It has been extensively validated for its use in clinical trials in combination with the EULAR response criteria. The original DAS included the Ritchie articular index, the 44 swollen joint count, the ESR and a general health assessment on VAS. After validation of the 28 non-graded joint count for tenderness and swelling, DAS 28 has been developed including 28 joint counts. The results of DAS and DAS28 are not directly interchangeable.

[0090] Using the DAS, several thresholds have been developed for high disease activity, low disease activity or even remission. Also, response criteria have been developed based on DAS, so when the DAS of a patient is measured at two time points, the clinical response can be assessed.

[0091] Disease variables needed to calculate the DAS28 are: swollen joint count (28 joints); tender joint count (28 joints); ESR (mm after 1 hour); Patients general health (GH) or global disease activity (visual analogue scale (VAS) of 100 mm) – in this study named Patient's Global Assessment of Disease Activity. Twenty-eight tender and swollen joint scores include the

following joints: shoulders, elbows, wrists, metacarpophalangeal joints, proximal interphalangeal joints and the knees.

[0092] The formula used to calculate the DAS is the following:  $DAS28 = 0.56 * \sqrt{\text{tender28}} + 0.28 * \sqrt{\text{swollen28}} + 0.70 * \ln(\text{ESR}) + 0.014 * \text{GH}$ . The DAS provides a number on a scale from 0 to 10 indicating the current activity of the rheumatoid arthritis. A DAS28 above 5.1 means high disease activity and a DAS28 below 3.2 indicates low disease activity. Remission is achieved by a DAS28 lower than 2.6. Comparing the DAS28 from one patient on two different time points, it is possible to define improvement or response.

[0093] Patient's Assessment of Pain and Patient's Global Assessment of Disease Activity are assessed using a horizontal visual analogue scale (VAS).

[0094] The Physician's Global Assessment of Disease Activity measures the patient's current disease activity using a 5 point graded scale (Likert scale) where 0=asymptomatic, 1=mild, 2=moderate, 3=severe and 4=very severe.

[0095] The Patient's Assessment of Physical Function is measured based on the patient's response to a Health Assessment Questionnaire (HAQ) which queries the patient regarding the patient's ability over the previous week to perform everyday tasks such as dressing and grooming, eating, walking, and whether the patient required aids or equipment to perform any of the aforementioned tasks.

[0096] The presence of morning stiffness is assessed by interviewing the patient and if present, the duration is recorded.

**CLAIMS**

What is claimed is:

1. A method for treatment of rheumatoid arthritis in a patient comprising administering to the patient a composition comprising a fusion molecule comprising:
  - (i) TACI extracellular domain or fragment thereof which binds BlyS; and
  - (ii) a human immunoglobulin-constant domainin an amount effective to treat said arthritis.
2. The method of claim 1, wherein said TACI extracellular domain has a sequence set out as SEQ ID NO: 1.
3. The method of claim 1, wherein said TACI extracellular domain is at least 50 % identical to SEQ ID NO: 1.
4. The method of claim 1, wherein said human immunoglobulin-constant domain has a sequence set out as SEQ ID NO: 2.
5. The method of claim 1, wherein said composition is administered in amount of about 0.01 mg per 1 kg of patient's body weight to about 10 mg/kg body weight.
6. The method of claim 5, wherein said composition is administered in said amount 7 times during a twelve-week interval.
7. The method of claim 5, wherein said composition is administered in said amount 7 times during a twelve-week interval, followed by additional administrations of said composition at said amount.
8. The method of claim 5, wherein said composition is administered in said amount 3 times during a four-week interval.

9. The method of claim 5, wherein said composition is administered in said amount 3 times during a four-week interval, followed by additional administrations of said composition at said amount.

10. The method of claim 5, wherein said composition is administered in said amount every other week for 2 to 30 weeks.

11. The method of claim 1, wherein said method further comprises co-administering to the patient a second medicament.

12. The method of claim 11, wherein said second medicament is selected from the group consisting of: hydroxychloroquine, sulfasalazine, methotrexate, leflunomide, rituximab, infliximab, azathioprine, D-penicillamine, Gold (oral or intramuscular), minocycline, cyclosporine, a corticosteroid, a non-steroidal anti-inflammatory drug (NSAIDS), a cytokine, an anti-cytokine and an interferon.

13. The method of claim 1, wherein said composition is administered subcutaneously, orally or intravenously.

14. The method of claim 1 in which the patient is a human.
